***ABSTRACT\_** The current research aimed to identify differences in wellbeing with its three dimensions (interactive allergies, paranoia and hostility) according to the prevailing professional tendencies among social realist in the Holland scale. The researcher followed the descriptive method by selecting a random sample consisting of 175 students at the secondary level schools in the city of Latakia in Syria. Two tests were used to reach the objectives of the research: Strong interest inventory, and the measure of Wellbeing with the dimensions of interactive allergies, paranoia and hostility. The results indicated that 44.6% of respondents tend to the social pattern and 53.1% tend to realistic pattern professional, while 2.3% of respondents did not tend to any pattern without the other. The results also showed that the sample that did not show a trend towards specific professional tendencies pattern shown problems in mental health compared to individuals who have demonstrated a realistic socially or professionally inclined. Individuals also showed that people with social interactive pattern is less sensitive than people with a realistic style individuals, while individuals with realistic style were less suffering from symptoms of paranoia in comparison with other people with social pattern. The hostility did not show differences between respondents, according to the three patterns.*
